

DESCRIPTION

PHOTOELECTRIC CONVERTING APPARATUS

5 TECHNICAL FIELD

The present invention relates to a photoelectric converting apparatus such as a radiation image pickup apparatus, and more particularly to a photoelectric converting apparatus designed for reducing sensitivity loss resulting from a parasitic capacitance.

10

BACKGROUND ART

There is already known a photoelectric converting apparatus such as a radiation image pickup apparatus which reads a charge produced by photoelectric conversion in a photoelectric converting element of a sensor array utilizing amorphous silicon or polysilicon, by transfer of the charge to a capacitance by means of a matrix drive.

Fig. 9 is a schematic circuit diagram showing a prior photoelectric converting apparatus (radiation image pickup apparatus). In the prior photoelectric converting apparatus, as shown in Fig. 9, a pixel indicated by a broken-lined frame includes a PIN photodiode PD and a selecting thin film transistor (TFT) ST, and a number of such pixels are arranged two-dimensionally to constitute a sensor array 101. Such device is constituted for example of an amorphous silicon layer and a polysilicon layer, formed on a glass substrate 102. The PIN diodes PD of the pixels receive, at common electrodes thereof, a bias voltage V_s from a power source.

Also gate electrodes of the selecting TFTs ST of the pixels are connected to common gate lines V_{g1} - V_{gM} . The common gate lines V_{g1} -

VgM are connected to a gate driver 104 provided with a shift register (not shown). Source electrodes of the selecting TFTs ST of the pixels are connected to common signal lines Sig1 - SigN. The common signal lines Sig1 - SigN are connected to a readout circuit 103 provided with amplifiers Amp1 - AmpN, an analog multiplexer MUX and an A/D converter (not shown).

The prior photoelectric converting apparatus of such structure executes a matrix drive by the gate driver 104, whereby photographed image data are outputted to the readout circuit 103 and are read out.

In the following, there will be explained a cross-sectional structure of a sensor array employed in the prior photoelectric converting apparatus such as a radiation image pickup apparatus. Fig. 10 is a cross-sectional view showing a pixel of a prior photoelectric converting apparatus (X-ray image pickup apparatus).

On a glass substrate 201, in each pixel, a gate electrode layer (lower electrode) 202, an insulation layer (amorphous silicon nitride film) 203, an amorphous silicon semiconductor layer 204, an amorphous n-silicon layer 205, and a source/drain electrode layer (upper electrode) 206 are laminated to constitute a selecting thin film transistor (TFT) 222. Also on the glass substrate, an extended portion (lower electrode) of the source/drain electrode layer 206, an amorphous p-silicon layer 207, an amorphous silicon semiconductor layer 208, an amorphous n-silicon layer 209 and an upper electrode layer 210 are laminated to constitute a photodiode 221. Further on the glass substrate 201, there is present a wiring portion 223 constituted by laminating the insulation layer 203, the amorphous silicon semiconductor layer 204, the amorphous n-silicon layer 205, and the source/drain electrode layer 206. Also a protective layer 211 constituted for example of an amorphous silicon nitride film is so formed as to cover these components, and a phosphor

layer (not shown) is adhered thereon by an adhesive layer 212. Such structure is described for example in Japanese Patent Application Laid-open No. H08-116044.

5 The phosphor layer is provided for converting incident radiation (X-rays) into visible light. In general, a photodiode formed with amorphous silicon has an extremely low sensitivity to X-rays. The phosphor layer is constituted for example of a gadolinium-based material or of CsI (cesium iodide).

10 In such prior photoelectric converting apparatus (X-ray image pickup apparatus), X-rays transmitted by an object are converted, upon entering the phosphor layer, into visible light. Then the visible light enters the photodiode. The photodiode generates a charge in the semiconductor layer, and such charges are transferred, when the TFTs are turned on, to the readout circuit in succession and are read out.

15 However, in the prior photoelectric converting apparatus such as the radiation image pickup apparatus, a large parasitic capacitance is generated in the common signal line as the number of pixels arranged two-dimensionally increases, thus leading to a significant decrease in the output voltage. More specifically, as shown in Fig. 9, a parasitic capacitance C_{gs} is present between
20 the gate and source electrodes of the selecting TFT ST, and the magnitude of the parasitic capacitance associated with a common signal line increases in proportion to the number of pixels connected to such common signal line. For example, in the case of preparing an area sensor corresponding to an X-ray film with a size of 40×40 cm by arranging pixels of 200×200 μm each by 2000
25 units in the longitudinal direction and by 2000 units in the lateral direction, even a parasitic capacitance C_{gs} of 0.05 pF in one location leads to a parasitic capacitance of $0.05 \times 2000 = 100$ pF per common signal line.

On the other hand, the photodiode PD has a sensor capacitance C of about 1 pF. Therefore, for a signal voltage V_1 generated in the photodiode in response to the entry of a visible light, an output voltage V_o observable on the common signal line becomes $V_o = V_1 \times C_s / (C_s + C_{gs}) \times 2000$, whereby the
5 output V_o becomes about 1/100 of the signal voltage V_1 .

Therefore, the prior photoelectric converting apparatus such as the radiation image pickup apparatus cannot be constructed into a sensor of a large area because of this significant loss in the output voltage. Also because of this loss in the output voltage, such apparatus is susceptible to the influence of noise
10 generated in the amplifiers of the readout circuit and of external noise, whereby a photoelectric converting apparatus of a high sensitivity may be difficult to construct. The influence of such noise may be reduced by providing the readout circuit with a constant current power source or low-noise amplifiers, but such low-noise amplifier, being a special circuit, leads to drawbacks such as
15 an increased cost. Also, since such low-noise amplifier generally has a high electric power consumption, the readout circuit will cause non-negligible heat generation.

DISCLOSURE OF THE INVENTION

20 An object of the present invention is to provide a photoelectric converting apparatus capable of reducing the influence of noise resulting from a parasitic capacitance, and readable with a readout circuit of a simple configuration with a low electric power consumption.

The present inventor, as a result of intensive investigations for
25 resolving the aforementioned drawbacks, has reached the present invention in the following embodiments.

A photoelectric converting apparatus of the present invention has a

photoelectric converting element, a resetting transistor in which a source is connected to the photoelectric converting element and a drain is connected to a resetting power source, a readout transistor in which a gate is connected to the photoelectric converting element and a drain is connected to a readout power
5 source, a signal line connected to a source of the readout transistor, a selecting transistor connected between the readout power source or the signal line and the readout transistor, and a constant current source connected to the signal line.

An X-ray image pickup system of the present invention has such a photoelectric converting apparatus as just described, an X-ray generating
10 apparatus and control means, in which the control means controls functions of the X-ray generating apparatus and the photoelectric converting apparatus to read an X-ray image formed by X-rays that have been transmitted through an object.

According to the present invention, it is possible, even in a sensor of a
15 large area, to suppress a loss in the output voltage resulting from an increase in the parasitic capacitance. Therefore the sensor is less susceptible to the influence of noise, and can provide a high sensitivity. Also a readout means can be constructed without employing a special circuit such as a low-noise amplifier or a special constant current source. Also a readout means can be
20 constructed with low electric power consumption and with little troublesome heat generation. Furthermore, the constant current source employed in the present invention can be formed by a thin film transistor on a glass substrate. Therefore, it can be formed by means of film formations simultaneously with the photoelectric converting element and other thin film transistors, thus being
25 advantageous in cost. Also the constant current source can be provided in a distant location from the readout means on the glass substrate, thereby alleviating the influence of the resistance of the signal line.

Other features and advantages of the present invention will become apparent from the following description taken in conjunction with the accompanying drawings, in which like reference characters designate the same or similar parts throughout the figures thereof.

5

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying drawings, which are incorporated and constitute a part of the specification, illustrate embodiments of the invention and, together with the description, serve to explain the principles of the invention.

25 BEST MODE FOR CARRYING OUT THE INVENTION

In the following, the present invention will be clarified in more details by embodiments thereof, with reference to the accompanying drawings.

(First embodiment)

At first there will be explained a first embodiment of the present invention. Fig. 1 is a circuit diagram showing a circuit structure of a photoelectric converting apparatus, particularly an X-ray image pickup apparatus, constituting the first embodiment of the present invention.

In the present embodiment, a sensor array 1 is constructed on a glass substrate 2, by arranging four pixels PE11, PE12, PE21 and PE22 in two rows and two columns, but the number of pixels constituting the sensor array 1 is not limited to such example. Each pixel is provided with a photoelectric converting element PD constituted of a PIN photodiode formed with amorphous silicon, and a storage capacitance Cs for accumulating a signal charge generated by the photoelectric converting element PD. The photoelectric converting element PD and the storage capacitance Cs are grounded at one terminal thereof and are mutually connected at their other terminal. Each pixel is further provided with a resetting MOS transistor RT, a selecting MOS transistor ST and a source-follower MOS transistor (readout transistor) FT. The resetting MOS transistor RT, the selecting MOS transistor ST and the source-follower MOS transistor FT are constituted of thin film transistors formed for example with amorphous silicon or polysilicon. The storage capacitance Cs may be dispensed with in a case where the photoelectric converting element PD itself has a sufficiently large capacitance.

A common resetting line R1 is commonly connected to gates of the resetting MOS transistors RT of the pixels PE11 and PE 12, and a common resetting line R2 is commonly connected to gates of the resetting MOS transistors RT of the pixels PE21 and PE 22. Also each resetting MOS transistor RT is connected at one end thereof to a resetting power source 5, and at the other end to the photoelectric converting element PD and the storage

capacitance Cs.

A common selecting line S1 is commonly connected to gates of the selecting MOS transistors ST of the pixels PE11 and PE 12, and a common selecting line S2 is commonly connected to gates of the selecting MOS transistors ST of the pixels PE21 and PE 22. Also each selecting MOS transistors ST is connected at one end thereof to a source follower power source (readout power source) 6, and at the other end to a drain of the source follower MOS transistor FT in the same pixel.

A common signal line Sig1 is commonly connected to sources of the source-follower MOS transistors FT of the pixels PE11 and PE 21, and a common signal line Sig2 is commonly connected to sources of the source-follower MOS transistors FT of the pixels PE12 and PE 22. Also a gate of each source-follower MOS transistors FT is connected to the photoelectric converting element PD and the storage capacitance Cs in the same pixel.

The common resetting lines R1 and R2, and the common selecting lines S1 and S2 are connected to a scanning circuit 4 provided with a shift register formed with crystalline silicon. Also the common signal lines Sig1 and Sig2 are connected to a readout circuit 3 formed with crystalline silicon. Further, the common signal lines Sig1 and Sig2 are connected to a constant current source I formed on the glass substrate 2. The readout circuit 3 is provided with amplifiers Amp1 and Amp2 respectively for the common signal lines Sig1 and Sig2, and also with an analog multiplexer MUX for outputting these output signals in succession to the exterior. The sensor array 1 is provided, on a light receiving surface thereof, with a phosphor layer similar to that in the prior configuration.

In the following, functions of the photoelectric converting apparatus (X-ray image pickup apparatus) of the first embodiment will be explained.

Fig. 2 is a timing chart showing functions of the photoelectric converting apparatus (X-ray image pickup apparatus) of the first embodiment. In Fig. 2, R1 and R2 indicate resetting pulses respectively applied to the gates of the resetting MOS transistors RT through the resetting lines R1, R2, while S1 and S2 indicate selecting pulses respectively applied to the gates of the selecting MOS transistors ST through the selecting lines S1, S2, and MUX_CLK indicates a pulse supplied to the analog multiplexer MUX.

In a state where radiation (X-rays) continuously irradiates the photoelectric converting apparatus, when the scanning circuit 4 applies a resetting pulse to the common resetting line R1, the photoelectric converting elements PD of the pixels PE11 and PE12 are reset in the potential and start a photoelectric conversion, thereby accumulating charges in the storage capacitances Cs. Also when the scanning circuit 4 applies a resetting pulse to the common resetting line R2, the photoelectric converting elements PD of the pixels PE21 and PE22 are reset in the potential and start a photoelectric conversion, thereby accumulating charges in the storage capacitances Cs.

Then, when the scanning circuit 4 applies a selecting pulse to the common selecting line S1, after the application of the resetting pulse to the common resetting line R1, the signal charges accumulated in the storage capacitances Cs of the pixels PE11 and PE 12 after the resetting of the photoelectric converting elements PD are read out through the signal line Sig1 to the readout circuit 13. Similarly, when the scanning circuit 4 applies a selecting pulse to the common selecting line S2, after the application of the resetting pulse to the common resetting line R2, the signal charges accumulated in the storage capacitances Cs of the pixels PE21 and PE 22 after the resetting of the photoelectric converting elements PD are read out through the signal line Sig2 to the readout circuit 13.

The readout circuit 3 outputs, in synchronization with the pulses MUX_CLK, the signals supplied through the signal lines Sig1 and Sig2 to an external processing apparatus or the like.

In such first embodiment, the entire circuit has a source-follower
5 circuit structure. Therefore the signals obtained in the photoelectric
converting elements PD can be amplified and read out without being influenced
by the parasitic capacitances P on the signal lines Sig1 and Sig2. It is
therefore possible to avoid an output loss resulting from a large sensor area
formation. There can also be obtained an effect that the output is less
10 susceptible to noise generated in the amplifiers Amp1, Amp2 themselves in the
readout circuit or to external noise. A high sensitivity can thus be obtained.
Furthermore, as the signal obtained by the photoelectric converting element PD
is amplified by a source follower and the readout circuit 3 does not require a
constant current source, the readout circuit 3 can have a simple configuration
15 and can be constructed with inexpensive general-purpose elements. Thus the
readout circuit can be realized with a simple structure not requiring special
components such as a low-noise amplifier of a high electric power consumption
or a constant current source, which are necessary in the prior technology.

In the foregoing description of the functions, the radiation (X-rays) is
20 assumed to irradiate the device continuously, but the irradiation may also be
intermittent. Also, in the structure of the X-ray image pickup apparatus, the
selecting MOS transistor may be provided at the side of the source of the
source-follower MOS transistor. Also, the constant current source is not
particularly restricted in the circuit configuration and can be constituted with
25 one or more TFTs.

(Second embodiment)

In the following, there will be explained a second embodiment of the

present invention. Fig. 3 is a circuit diagram showing a circuit structure of a photoelectric converting apparatus, particularly an X-ray image pickup apparatus, constituting a second embodiment of the present invention. In the second embodiment, in place for the constant current source I employed in the first embodiment, a thin film transistor (TFT) CT formed by amorphous silicon is provided. A gate of the thin film transistor CT receives a voltage from a power supply 7 for a constant current source. Such structure can be produced by a simple manufacturing process, as the constant current source can be simultaneously formed by means of film formations with other transistors (resetting, selecting and source follower). The thin film transistors for resetting, for selecting, for source follower and for constant current source may have same laminated film thicknesses or individually different film thicknesses. They may also have common impurity doping conditions (n type or p type) or individually different doping conditions. Furthermore, they may be formed with amorphous silicon in a part and polysilicon in another part, utilizing for example laser annealing.

In Fig. 3, the constant current source having the thin film transistor CT and the power supply 7 for the constant current source is constructed as shown in Fig. 11. In this case, the thin film transistor CT constituting the constant current source may be of n-type or p-type.

In a case where the thin film transistor CT is for example an n-type thin film transistor, the thin film transistor CT shows V_{ds} - I_{ds} characteristics as shown in Fig. 4, with respect to a source-drain voltage V_{ds} , a source-drain current I_{ds} , a gate-source voltage V_{gs} and a threshold voltage V_{th} . Therefore, the thin film transistor CT can be utilized as a constant current source by controlling the gate voltage of the thin film transistor CT so as to bring it to a saturation region satisfying a relation ($V_{ds} > V_{gs} - V_{th}$).

Also according to the aforementioned relationship, in a case where the thin film transistor is n-type, the constant current source can be realized with a simple structure by mutually connecting the gate and the source as shown in Fig. 12. Also depending upon the required current, a resistor may be provided
5 between the gate and the source as shown in Fig. 13. The configuration shown in Fig. 12 or 13 allows to dispense with the power supply for the constant current source.

Also another example of the constant current source formed on the glass substrate is shown in Fig. 14. In this example, a pseudo constant current
10 source is formed by a resistor patterned on the glass substrate, without employing a thin film transistor or the like. The resistance in this case is preferably sufficiently larger than an on-resistance of the selecting MOS transistor.

(Third embodiment)

15 In the following, there will be explained a third embodiment of the present invention. Fig. 5 is a circuit diagram showing a circuit structure of a photoelectric converting apparatus, particularly an X-ray image pickup apparatus, constituting a third embodiment of the present invention. In contrast to the second embodiment, in which the thin film transistor CT
20 constituting the constant current source is positioned between a pixel and the readout circuit 3, in the third embodiment, the thin film transistor CT is located, on the common signal line, at a position more spaced from the readout circuit 3 than the pixel. Stated differently, the pixel is positioned between the thin film transistor CT and the readout circuit 3.

25 An advantage of a spaced arrangement of the constant current source from the readout circuit will be explained with reference to Figs. 15, 16 and 17. Fig. 15 shows a structure in which, for each signal line, the constant current

source is spaced from the readout means, and Fig. 16 shows a structure in which the constant current source is positioned at the side of the readout means. In case the constant current source is provided at the side of the readout means as shown in Fig. 16, a voltage V_{out} actually read out by the readout means is lowered from the source potential V_s of each source follower MOS transistor by resistance components R_1 , R_2 and R_3 of the signal line. For example, in the case of reading out pixel C, there is read a voltage lower than the source potential of the FT3 by $\Delta V = I_0 \times (R_1 + R_2 + R_3)$.

Such voltage drop is not negligible in a case where the signal line has a large resistance, for example when a photoelectric converting apparatus of a large area is constructed. Fig. 17 shows a state of voltage drop by the pixel. On the other hand, a spaced arrangement of the constant current source from the readout means allows one to avoid the drop in the output voltage resulting from the resistance of the signal line. For example, also in the case of reading pixel C, current scarcely flows in the resistance components R_1 , R_2 and R_3 , so that the source voltage of the source follower MOS transistor can be read by the readout means almost without a voltage drop. Fig. 17 also shows that the voltage drop is quite slight when the constant current source is spaced from the readout means. The spaced arrangement of the constant current source from the readout means as shown in Figs. 5 and 15 allows to avoid the drawback such as the voltage drop even in case the resistance of the signal line is not negligible as in a photoelectric converting apparatus of a large area.

The present embodiment can further provide, in addition to the effects obtained in the first and second embodiments, an effect of avoiding a voltage drop on the signal output, to be read by the readout circuit 3, resulting from a resistance component even when such resistance component is present in the common signal line.

(Fourth embodiment)

In the following, there will be explained a fourth embodiment of the present invention. Fig. 6 is a circuit diagram showing a circuit structure of a photoelectric converting apparatus, particularly an X-ray image pickup apparatus, constituting a fourth embodiment of the present invention. In contrast to the third embodiment, the fourth embodiment is provided with a readout scanning thin film transistor (TFT) RDT in each of the common signal lines Sig1, Sig2. The readout scanning thin film transistor RDT is formed between the pixel on the glass substrate 2 and the readout circuit 3. Also, the readout circuit 3 is not provided with the analog multiplexer MUX and the output signals from the signal lines are entered into a single amplifier Amp. The readout circuit 3 is further provided with a readout scanning circuit 8 for scan controlling the gate voltages of the readout scanning thin film transistors RDT.

In the fourth embodiment of the aforementioned structure, after the signal charges are accumulated in the storage capacitances Cs as in the first embodiment, the readout scanning thin film transistors RDT are turned on in synchronization with a clock signal CLK1 for the signal line Sig1 and a clock signal CLK2 for the signal line Sig2 as shown in Fig. 7, whereby the accumulated charges are read out in succession to the readout circuit 3.

In such fourth embodiment, the readout circuit 3 only requires an amplifier and other necessary logic circuits and is thus further simplified in structure, whereby the noise is further reduced and a higher sensitivity can be obtained with a simpler configuration. In the present embodiment, in consideration of the scanning speed, the scanning thin film transistors RDT are preferably formed by polysilicon, utilizing for example a laser annealing method.

(Fifth embodiment)

In the following, there will be explained a fifth embodiment of the present invention. Fig. 8 is a circuit diagram showing a circuit structure of a photoelectric converting apparatus, particularly an X-ray image pickup apparatus, constituting a fifth embodiment of the present invention. In contrast to the fourth embodiment in which the selecting MOS transistor ST is connected to the drain of the source follower MOS transistor FT, in the fifth embodiment, the selecting MOS transistor ST is connected between the source of the source follower MOS transistor FT and the signal line Sig1 or Sig2.

10 The drain of the source follower MOS transistor FT is directly connected to the source follower power source 6.

Such fifth embodiment can provide an effect similar to that of the fourth embodiment.

The apparatus is not limited to X-ray detection but may directly receive visible light, in which case the phosphor layer can be dispensed with. Also, the photoelectric converting element is not limited to a PIN photodiode but may also be constituted of a MIS sensor. In case of utilizing a MIS sensor, there may also be employed a configuration in which the resetting power source connected to the resetting transistors can control the output voltage by

20 unillustrated control means.

Further, the photoelectric converting element may be so-called direct converting element based on a material capable of directly absorbing radiation (or X-rays) and generating a charge, such as amorphous selenium, gallium arsenide, lead iodide or mercury iodide. In such case, the photoelectric

25 converting element can be constructed by forming or connecting such direct converting element on a glass substrate on which the thin film transistors are formed with amorphous silicon or polysilicon.

(Sixth embodiment)

In the following, there will be explained a sixth embodiment of the present invention, which is an X-ray image pickup system utilizing the photoelectric converting apparatus of the present invention. Fig. 18 illustrates
5 an X-ray image pickup system of the sixth embodiment of the present invention.

In an X-ray room (image pickup room), X-rays 6060 generated by an X-ray tube (X-ray generating apparatus) 6050 are transmitted through a chest 6062 of a patient or a person 6061 being examined and enter an image sensor 6040. The entering X-rays contain information of the interior of the body of
10 the patient 6061. In response to the X-ray entry, a scintillator (phosphor) generates light, which is photoelectrically converted by photoelectric converting elements of a sensor panel to obtain electrical information. The image sensor 6040 outputs such information as an electrical signal (digital signal) to an image processor 6070. The image processor 6070, serving as
15 image processing means, applies an image processing on the received signal and outputs it to a display 6080 constituting display means in a control room (operation room). Thus a user can obtain information on the interior of the body of the patient 6061, by observing the image displayed on the display 6080. The image processor 6070 also has a control function, and can switch
20 moving/still image modes or can control the X-ray tube 6050.

Also, the image processor 6070 is capable of transferring the electrical signal outputted from the image sensor 6040, to a distant location through transmission means such as a telephone line 6090, for display on display means 6081 in another location such as a doctor room. It can also store the electrical
25 signal from the image sensor 6040 in recording means such as an optical disk, which can be utilized for a diagnosis by a doctor in another location. The signal can also be recorded on a film 6110 by a film processor 6100

constituting recording means.

The present X-ray image pickup system is featured by the following points:

(1) The aforementioned photoelectric converting apparatus is provided in
5 the image sensor 6040, and the A/D converted digital output is subjected to a
suitable image processing by the image processor 6070; and

(2) The image processor 6070 is provided with unillustrated control means,
which controls the image sensor 6040, the X-ray generating apparatus 6050, the
displays 6080, 6081, the film processor 6100, etc.

10 As many apparently widely different embodiments of the present
invention can be made without departing from the spirit and scope thereof, it is
to be understood that the invention is not limited to the specific embodiments
thereof except as defined in the claims.
